

String Formatting in Python

Outcomes of this Lecture

How to use index mechanism in format method?

How to assign names for variables in format method?

How to implement alignment in format method?

How to use fstrings?

Types of String Formatting

1. Formatting with **% operator**.
2. Formatting with **string.format()** method.
3. Formatting with string literals **(f-strings)**.

FORMATTED STRING LITERALS (FSTRINGS)

- The new string formatting mechanism introduced in python 3.6 is known as formatted string literals or more commonly as **F-strings**.
- To create an f-string in Python, prefix the string with the letter “f” or “F”.
- Hence, it is called F-strings.
- **Syntax: `print(f 'my name is {Variable_name} ' )`**

fstrings

- Fstrings are faster than the other two methods.
- This new formatting syntax is powerful because you can embed Python expressions in fstrings, will be evaluated inline with fstrings.
- `a=10; b=20`
- `print(f 'sum of a and b is {a+b}')`
